“A thermal noise’s analysis in biological matter”

Abstract

The biological effects of electromagnetic fields of very low intensity (two or three orders of magnitude lower than $kT$), found by many researchers, and of low frequency magnetic fields, whose energy is ten orders of magnitude lower than $kT$, are one of the most important topics of bioelectromagnetism. The physical nature of such phenomena is still unclear.

In 1990, the physicist Adair tried to solve this problem by suggesting that no biological effect is possible. The paradigm is the constraint of thermal limits, and it is based on the analysis of Johnson and Nyquist noise and the hypothesis of noise electric field. This point of view became the prevailing one in the well known APS statement of 1995. Nowadays this paradigm is the basic problem for those scientists who research about bioelectromagnetism.

The authors show, through a detailed physical analysis of the thermal noise’s theory, that Adair’s paradigm depends on some misconceptions, that could affect its validity and the results of Adair’s analysis. Consequently, they propose another path to interpret this kind of phenomena inside the biological matter.

Massimo Scalia; associated professor at the Faculty of Math.Phys. and Nat. Sciences of “La Sapienza” University of Rome is the responsible of an Ateneo Federato research on non linear dynamical systems theory and its applications to Mechanics, Climatology and Biology, in particular modelling interactions between electromagnetic fields and biological matter and the study of the role of thermal noise. He has proposed a method for electromagnetic characterizing of environment, successfully applied in field research.

Massimo Sperini; professor of Electronics at “E. De Amicis” Institute (a public high school in Rome) is a research collaborator of Massimo Scalia. He has projected, realized and successfully employed several electronic instruments to measure characteristic electromagnetic quantities, in particular a ionmeter with a very high resolution power. He is able to perform very delicate measures of biological and physiological parameters (membrane potential, resistance, impedance ecc.).

Fabrizio Guidi; professor of Authomatic Electronic Systems at “G. Vallauri” Institute (a public high school in Rome) is a research collaborator of Massimo Scalia, who has intended to the major part of both theoretical and experimental researches.
